## COVID-19 and Kids

Our understanding of COVID-19 and children continues to emerge. This is what we know.

**CO** = corona  
**VI** = virus  
**D** = disease  
**19** = 2019

Children can get and spread COVID-19

COVID-19 rarely causes severe illness in children and very rarely causes death. There have been no deaths in children in Australia under 10 years

Children who have COVID-19 usually have mild symptoms, similar to a cold. Some have no symptoms

Common symptoms include tiredness, a headache, cough, fever or sore throat

Children who have symptoms should be tested for COVID-19

People may become infected by touching surfaces contaminated with the virus then touching their eyes, nose or mouth

The virus is spread through tiny droplets from an infected person's nose or mouth when they cough, sneeze, speak or breathe

The COVID-19 Delta variant spreads more quickly than previous variants

Children - like adults - can protect themselves and others from the virus by washing their hands, covering their mouth/nose when coughing and staying home if unwell

Masks are effective at reducing the spread of COVID-19

Free and safe vaccines are available in Australia for everyone aged 12 years and over

Vaccinations are not yet approved for children under 12 years. Clinical trials are underway.

The social isolation, lockdowns, school closures, and family financial hardship associated with the pandemic affects children's health and wellbeing

Children experiencing disadvantage or who have pre-existing health conditions are at greater risk of severe disease
